

Observatory

Isabella, Kevin, Mandi,
Liliana, Hiro, Alicia

Introduction

Our group created an observatory because we were interested in space. Our original idea was a telescope but we realized we did not have enough parts, so we went with making an observatory.

We did both a static and thermal FEA as we really wanted to see if our observatory would be able to handle the conditions that we applied to it.

We animated all of the moving parts, including the top dome, and both translational and rotational parts of the telescope, and the doors.

Our new feature is the 3D Sketch tool, allowing us to create a whole part with one sketch.

We used reference images and a reference model, but no tutorial videos to help us create the model.

Main Assembly

Main Assembly

ITEM NO.	PART NUMBER	QTY.
1	Floor	1
2	observatory base	1
3	Door Waist	1
4	Door	2
5	Inside Railing	1
6	Inside Stairs	1
7	dome holder final	1
8	outer dome final	1
9	inner dome final	1
10	pin cap	1
11	Door Handle	4
12	Telescope and Stand Assembly	1
13	Outside Stairs (3D sketch)	1
14	Outside Railing (Single)	2
15	pin final	1
16	Window	2

Scale:

1 :300

Animation

- Chose inner and outer dome plates and telescope base to show rotational motion
- Chose telescope and telescope sliders to show translational (vertical) motion
- Key takeaway: make a subassembly flexible first to move in the main assembly

Thermal FEA

We wanted to know how well insulated this building is to see if the observatory would be able to keep the telescope in ideal conditions. We made the outside 10° F to represent a cold day in Maryland and the inside 67° F to represent a heated observatory. After running the FEA we see that the observatory is able to keep the telescope at 67° F or ~19° C. This shows that the observatory is able to keep the telescope at ideal conditions in Maryland. We could improve the wall thickness or material in order to insure that the observatory is insulated enough

Static FEA (Stress)

We did this static FEA in order to figure out what happens if a huge load is applied to our dome and how that affects the rest of the building. For this FEA we put a load of 10,000,000N on the top pin and fixed the base of the observatory. The only place that felt stress was at the top near the pin and the max stress it felt was 234.1 N/mm². We used galvanized steel which has a yield strength of 203.9 N/mm². This means that with a force of 10,000,000 N it will finally fail - which is completely unreasonable to expect from air pressure – meaning that the dome would not fail under normal loading.

Static FEA (Displacement)

Our dome had a max displacement of 17.84mm on the pin and right next to the pin. Knowing this we could improve our design by adding supports to the bottom of the dome or get an even stronger material.

New feature

- 3d sketch
- Construction lines for viewing reference
- Helpful tool to see how your part will look before adding feature

New feature

- Draft
- Tapers selected faces
- Helpful as a time saver, can also be used in the extrude menu

Draft

Tapers model faces by a specified angle, using a neutral plane or a parting line. Draft is often used to make a molded part easier to remove from the mold.

Reflections

Overall, the observatory was a really fun project that we all enjoyed working on.

- One of the problems that occurred most often was ensuring that everything was properly scaled before we assembled the parts in the final model.
- We spent a lot of time learning how to design the parts so they looked more realistic and like a proper telescope and observatory. Being able to look at reference photos was a huge help. Taking the extra steps to make our model look more visually appealing in SolidWorks was another learning curve; however, we believe this extra time taken paid off in the end.
- We also could have spent more time defining proper materials for our parts that mirror their real-world counterparts
